#### Abstract

Fatty acid binding protein (FABP4) inhibitors are of synthetic and therapeutic interest and ongoing clinical studies indicate that they may be a promise for the treatment of cancer, as well as other diseases. As part of a broader research effort to develop more effective FABP4 inhibitors, we sought to identify new structures through a two-step computing assisted molecular design based on the established scaffold of a co-crystallized ligand. Novel and potent FABP4 inhibitors have been developed using this approach and herein we report the synthesis, biological evaluation and molecular docking of the 4-amino and 4-ureido pyridazinone-based series.

## 1. Introduction

Fatty acids (FAs) are long carbon chain organic carboxylic acids responsible for different actions in the human organism [1,2]. Their chronic high concentration in circulation leads to various disorders [3,4], including atherosclerosis [5], diabetes [6] and obesity [7]. Considering that their chemical structure is characterized by high lipophilicity, FAs are insoluble in water, and their trafficking into the body requires specific carriers such as the fatty acid-binding proteins (FABPs). [8]. Since their discovery, FABPs have been classified into different families based on their localization in the human body, such as A-FABP (adipocyte), B-FABP (brain), E-FABP (epidermal), H-FABP (muscle and heart), I-FABP (intestinal), Il-FABP (ileal), L-FABP (liver), M-FABP (myelin), and T-FABP (testis). FABP4 (aP2 or A-FABP) is the subtype expressed in adipocytes [9], and the research into small molecule inhibitors for such protein initially started when it was reported that knockout animal models of FABP4 produced protective effects against the development of insulin resistance [10], as well as several pathological events linked to the metabolic syndrome and atherosclerosis [11-13]. Interestingly, pharmacological approaches with small molecules that inhibit the normal function of the protein are also valid in this regard, demonstrating similar results as the genetic procedures by mimicking the phenotype of FABP4-deficient mice [14]. This family of transporter proteins also has a role in cancer progression [15], and it was discovered that non-physiological expressions of FABPs are present in some of the most common cancers such as renal cell carcinoma, bladder and prostate, as well as other types of cancer cells [16-18]. It was recently discovered that FABP4 promotes the metastasis and invasion of colon cancer and that the treatment with a classical small molecule
inhibitor (BMS309403) weakened the migration and invasion of colon cancer cells [19]. FABP4 leads also to abnormal metastasis patterns in ovarian cancer, and recent findings demonstrate that the protein is responsible for the disease's aggressivity, contributing to poor prognosis in this tumor [20]. Moreover, the transporter has also been shown to play a role in accelerating glioblastoma cell growth [21]. All these recent findings related to cancer research proved that FABP4 targeting may represent an effective and promising therapeutic strategy against oncological conditions, in addition to the established effects on metabolic and cardiovascular diseases.

Recently, a variety of effective FABP4 inhibitors (FABP4i) have been developed, but unfortunately, none of them is currently in the clinical research phases [14,22]. Computeraided drug design represents a promising and effective tool for the identification of molecular hits as FABP4i [23-27]. In line with our recent interest in the development of new antitumor compounds and the identification of novel bioactive heterocycles [28-32], herein we report the design, synthesis and in vitro characterization of 4 -amino and 4 -ureido pyridazinone-based series of FABP4i inspired by the scaffold hopping of an established ligand co-crystallized within the protein.

## 2. Results and Discussion

### 2.1. Heterocyclic Small-Molecule Design

To generate a novel series of FABP4 inhibitors we have exploited a two-step computing assisted molecular design. As shown in Figure 1, in the first step of the drug-design process we focused on the search for bioisosteric-replacements/scaffold hopping of the pyrimidine scaffold of the co-crystallyzed ligand (2-[(2-oxo-2-piperidin-1 -ylethyl)sulfanyl]-6-(trifluoromethyl)pyrimidin-4-ol; pdbID: 1TOU). Our bioisosteric replacement analysis led to the selection of three nitrogen-containing heterocyclic frameworks, i.e., pyridazinones, pyridines and benzo[d]thiazole (see Supplementary Materials). Considering the synthetic accessibility of pyridazinone-based molecules and that pyridazinone was not investigated earlier as a scaffold to access FABP4 inhibitors, we envisaged to use this heterocycle to carry out automated ligand growing experiments inside the FABP4 cavity, as described in the Section 3, leading to 52 target molecules. The compounds were then synthesized and screened against FABP4 and the chemical structures are reported in Tables 1 and 2. Both the scaffold hopping and the ligand growing experiments were conducted using Spark (https:/ / www.cresset-group.com/products/spark/ accessed on 15 June 2022) [33].

### 2.2. Chemistry

The synthetic procedures carried out to obtain the target compounds containing the pyridazinone scaffold are reported in Schemes 1-9. The structures were confirmed on the basis of analytical and spectral data. Scheme 1 shows the synthetic pathway affording the final compounds $\mathbf{4 a , b}, \mathbf{5 a}, \mathbf{b}, \mathbf{6}$ and $\mathbf{7}$. Intermediate $\mathbf{2}$ [34] was obtained starting from isoxazole-pyridazinone $\mathbf{1}$, synthesized by adopting previously reported protocols [29-32] and using methanol and triethylamine for opening the isoxazole nucleus. The subsequent hydrolysis (acid 3 [35]) and acylation with thionyl chloride, triethylamine and appropriate amine led to final compounds $\mathbf{4 a}, \mathbf{b}$. Products $\mathbf{5 a}, \mathbf{b}$ were obtained from alkylation reaction of $\mathbf{4 a} \mathbf{a} \mathbf{b}$ with ethyl bromide in standard conditions. The opening of isoxazole core of the starting material 1 with $33 \% \mathrm{NH}_{4} \mathrm{OH}$ afforded to amide 6 [28] which, by subsequent dehydration with $\mathrm{POCl}_{3}$, led to compound 7. The synthesis of final compounds $\mathbf{1 6 - 1 8}$ is reported in Scheme 2. The reaction between sodium salt of diketone 8 with the commercially available ethyl chloro(hydroximino)acetate 9 in ethanol led to a mixture of isomers 10 and 11 [36] that were cyclized to isoxazole-pyridazinone 12 and 13 using phenylhydrazine and PPA. After chromatographic separation, the latter were subjected to a series of reactions to obtain the compounds 16-18. The treatment of intermediate $\mathbf{1 3}$ with ammonium formate and $\mathrm{Pd} / \mathrm{C}$ provided compound 18, while the treatment of 12 with methanol and triethylamine led to pyridazinone 14 . Intermediate 14 was first hydrolyzed to acid (15), then converted to amide (16) and finally treated with $\mathrm{POCl}_{3}$ to obtain the cyano derivative 17. The final compounds 21 and 22 were obtained through a procedure similar to that shown in Scheme 1 for amide derivative 6 and cyano derivative 7 , using intermediate 20 as the starting material, which was obtained by reaction of cyclohexyl hydrazine and PPA with isoxazole 19 [34] (see Scheme 3). Scheme 4 reports the synthesis of the pyridazinone-based derivatives of type 24 and 25 (unsubstituted at position 5), compound 28 and the thio-derivative 27. Intermediate 23 [37] was reacted with the appropriate brominated alkylating agent in presence of potassium carbonate and dry DMF to afford 24a-f derivatives (24a, [38]; 24c, [34]). The formation of urea derivatives of type $\mathbf{2 5}$ was carried out using sodium acetate and triphosgene in dry THF at reflux, and then treated with ammonia. The urea 28 was directly obtained from intermediate 23 using the same conditions used for compound type 25. The transformation of the carbonyl $(\mathrm{C}=\mathrm{O})$ in thiocarbonyl group $(\mathrm{C}=\mathrm{S})$ was carried out using the Lawesson's reagent in toluene (26) and the subsequently alkylation with methyl iodide in standard condition led to the thio derivative 27. In Schemes 5 and 6 are reported the synthetic procedures of other un-substituted pyridazinones at position 5, but bearing different groups/functions at position 4 and 6 . In particular, Scheme 5 depicts the synthetic pathways for compounds with a phenyl ring at position 6 and a methyl group at $\mathrm{N}-2$, while different substituents are introduced at position 4 . Starting from compound 24a [38] (Scheme 4), the amino group at position 4 was acylated using the suitable anhydride in pyridine in a sealed/pressure vessel to obtain the final compounds 29a-d. Moreover, the same amino group was also subjected to a coupling reaction using the appropriate

R-phenylboronic acid in presence of copper (II) acetate and triethylamine to furnish the derivatives $\mathbf{3 0 a}, \mathbf{b}$ and $\mathbf{3 3}$. The substituent R on the phenyl at position 4 was further elaborated. The $m / o-\mathrm{CN}$ group of compounds $\mathbf{3 0 a}, \mathbf{b}$ was converted into $\mathrm{m} / \mathrm{o}-\mathrm{CONH}_{2}$ (compounds 31a,b, respectively) with $80 \%$ sulfuric acid under reflux. The 4-carbethoxy function in product 33 was firstly hydrolyzed to acid 34 , converted into the corresponding acid chloride with thionyl chloride and then acylated with 1-acetylpiperazine (compound 35). Lastly, the carbonyl group of intermediate 24a was converted in thiocarbonyl (32) using the same procedure discussed in Scheme 4. In Scheme 6 are depicted pyridazinone-based derivatives with a methyl group or a hydrogen at $\mathrm{N}-2$, an amino group or urea functionality at position 4, but bearing different groups e/o functions (e.g., R-phenyl, alkyl, cycloalkyl) at position 6 . Starting from commercially available intermediates 36a-f, the introduction of an amino group at position 4 with hydrazine hydrate at high temperature led to compounds $37 \mathbf{a - e}(37 \mathbf{e},[38])$ and the subsequent alkylation with methyl iodide provided products 38ad. The derivatives $39 a, b$ and 40 were obtained from reaction with triphosgene and ammonia in the same conditions reported in Scheme 4 , starting from $\mathbf{3 8 b}, \mathbf{c}$ and 37 e, respectively. The direct alkylation of the intermediates 36 e and 36 f afforded the corresponding N -methyl derivatives 41a,b (41a, [39]), which were subsequently converted into compounds $\mathbf{4 2 a , b}$ through the same reaction used to obtain $37 \mathbf{a}-\mathbf{e}$. In particular, the reaction conditions used to introduce an amino group at position 4 led also to the reduction in the nitro group in compound $\mathbf{4 2 b}$. The latter was subjected to acylation reaction with acetyl chloride to obtain product 44. Instead, intermediate 42a was subjected to triphosgene treatment to obtain the urea derivative 43 . Scheme 7 reports the synthesis of final compounds 48 and 49. Intermediate 47 was obtained starting from isoxazole 45 , previously synthesized by us [34] by cyclization reaction with methyl hydrazine (46) and subsequent opening of the isoxazole ring with ammonium formate and palladium on carbon. The deacetylation (on 47) with $48 \%$ bromic acid at high temperature led to compound 48 , which was subsequently treated with triphosgene and ammonia to obtain the urea derivative 49. Compound 51 was obtained through alkylation reaction using standard conditions [40], but starting from product 50 [41] (Scheme 8). Lastly, the final compound 55 (Scheme 9) was obtained starting from intermediate 52 [42], through the same reactions of isoxazole nucleus opening ( 53 [42]), deacetylation (54 [43]) and formation of the urea function. In Scheme 9 is also illustrated the treatment of $\mathbf{5 2}$ with dimethylformamide dimethyl acetal to generate intermediate 56, which was subsequently converted into compound 57 using hydrazine hydrate.

Based on the analytical and spectral data (proton and carbon NMR) and mass spectrometry (MS), all the new compounds confirmed the predicted chemical structures, as well as satisfactory results in terms of formulation and purity (See Section 3; in Supporting Information are reported representative examples of analytical characterization data of the compounds processed to FABP4 inhibition assay in vitro). Reversed phase liquid chromatography was used to perform a qualitative analysis of the dataset's purity. The formation of the products was monitored by UV absorbance at wavelengths of 281 nm and 254 nm . The retention times range was from 6 to 17 min (See Section 3 and Supporting Information). The overall feature of mass spectra (LC-MS) of this series of pyridazinonederivatives is the presence of a predominant peak corresponding to the molecular ion $[\mathrm{M}+\mathrm{H}]^{+}$(See Section 3 and Supporting Information).

### 2.3. FABP4 Inhibition Evaluation

FABP4 inhibitory activity was assessed by measuring the decrease in fluorescent signal of a detection reagent (DR) when displaced by a strong FABP4 ligand. Specifically, the DR exhibits an increased fluorescence intensity when bound to FABP4. Therefore, any effective ligand of the protein, which binds to the same binding pocket and can displace the DR , determines a reduction in the fluorescence read-out. The new molecular series was screened in a two-step procedure. Firstly, a single concentration of $5 \mu \mathrm{M}$ was used to gain an estimation of the overall inhibitory effect of all the molecules. Subsequently, only the compounds that were able to reduce the fluorescence reading of at least $95 \%$ were further evaluated by measuring the $\mathrm{IC}_{50}$ values $(\mu \mathrm{M})$, which were lastly compared with the activity of the arachidonic acid (i.e., FABP4 established ligand). The single point displacement results are reported in Figure 2. Based on the data of the first screening, 10 molecules were selected as most effective compounds-i.e., able to reduce the fluorescence of the DR to at least $95 \%$, for which the $\mathrm{IC}_{50}(\mu \mathrm{M})$ was calculated. Arachidonic acid was used as a positive control, resulting with an $\mathrm{IC}_{50}$ of $3.42 \mu \mathrm{M}$. The $\mathrm{IC}_{50}$ values of our set of compounds are reported in Table 3. Compound 25a demonstrated a potent inhibitory activity, with an $\mathrm{IC}_{50}$ value (i.e., $2.97 \mu \mathrm{M}$ ) lower than the reference arachidonic acid.

### 2.4. Molecular Modelling Studies

Since the first apo-FABP crystal structure was published in 1992, many other holoFABP structures with a variety of ligands have been solved. The hydrophobic pocket side chains engage a hydrogen bond to the carboxylate of FAs toward several amino acids. Moreover, a network of water molecules may be involved in mediating these interactions. The docking experiments of the molecular series compounds were conducted on the most active compounds $\mathbf{4 b}, \mathbf{2 5 a}, \mathbf{3 0 b}$, and 22. Figure 3 shows the 2D binding interactions for the molecules, while Figure 4 displays the predicted poses inside the binding pocket of FABP4. All the compounds are able to engage several interactions with relevant residues in the binding pocket, such as R126 and Y128, as well as R106. R126 can interact with both the carbonyls of the most potent compound 25a, that also interacts directly with Y128 and, through the network of water molecules, with S53. The $\mathbf{4 b}$ is well allocated inside the binding pocket and is engaging a strong H-bond interaction with R126. Differently, compound 22 is not suitably allocated inside the pocket to generate appropriate binding with R126 and Y128 and most of the stabilizing interactions are due to pi-pi stacking with A75, F16 and M20. Lastly, the -CN group of 30b results responsible of the stabilizing interaction with R126 and Y128, that are likely to account for the lower activity of the compound, as determined by the lower binding interaction for this group with the residues.

## 3. Experimental Section

### 3.1. General Remarks

All the chemical reagents were purchased from Merk and Sigma Aldrich of reagent grade and were used without any further purification. Extracts were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvents were removed under reduced pressure. All reactions were monitored by thin-layer chromatography (TLC) using commercial plates (Merck) pre-coated with silica gel 60 F-254. Visualization was performed by UV fluorescence ( $\lambda \max =254 \mathrm{~nm}$ ) or by staining with iodine or potassium permanganate. Chromatographic separations were performed on silica gel columns by gravity (Kieselgel 40, 0.063-0.200 mm; Merck) or flash chromatography (Kieselgel 40, 0.040-0.063 mm; Merck). Yields refer to chromatographically and spectroscopically pure compounds, unless otherwise stated. When reactions were performed in anhydrous conditions, the mixtures were maintained under nitrogen atmosphere. Compounds were named following IUPAC rules as applied by Beilstein-Institut AutoNom 2000 (4.01.305) or CA Index Name. All melting points were determined on a microscope hot stage Büchi apparatus and are uncorrected. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra were obtained on a Bruker AVANCE 400 spectrometer at 400 MHz and 100 MHz , respectively, using 5 mm i.d. glass tubes. Chemical shifts ( $\delta$ ) values are expressed as parts per million (ppm) using DMSO $\left(\mathrm{d}_{6}\right)$ ( 2.50 for proton and 39.52 for carbon), methanol $\left(\mathrm{d}_{4}\right)$ ( 3.31 for proton and 49.00 for carbon) or $\mathrm{CDCl}_{3}$ ( 7.26 for proton and 77.16 for carbon) as solvents. The coupling constants (J) are reported in Hz . The following splitting patterns are identified: s, singlet; $d$, doublet; $t$, triplet; $m$, multiplet; or any combination of these e.g., dd, dt, etc. Analytical reversed-phase high performance liquid chromatography (reversed-phase HPLC) was conducted out on HP 1050 instrument (Agilent Technologies, Waldbronn, Germany) to ascertain the chromatographic purity of compounds. The system includes a quaternary pump, an autosampler, and a Kontron DEG 104 degasser (Kontron, Tokyo, Japan). A C 18 column, Zorbax, $80 \AA, 3.5 \mu \mathrm{~m}, 2.1 \times 100 \mathrm{~mm}$ was used with a total run time of 30 min . The mobile phase is composed of $0.1 \%$ Trifluoro acetic acid (TFA) in Milli-Q $\mathrm{H}_{2} \mathrm{O}$ and Acetonitrile (can) at a flow rate of $0.3 \mathrm{~mL} / \mathrm{min}$ with an injection volume of $10-30 \mu \mathrm{~L}$ [44]. The compounds were detected at 281 nm and 254 nm UV wavelengths. The values of the retention times ( $\mathrm{t}_{\mathrm{R}}$ ) are given in minutes. Mass spectrometry (LC-MS) experiments were performed on all the samples. The stock solutions ( $1 \mathrm{mg} / \mathrm{mL}$ in MeOH ) where diluted with $0.1 \% \mathrm{HCOOH}$ in $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}(50: 50)$ to a final concentration of $50 \mu \mathrm{~g} / \mathrm{mL}$ prior to analysis. The instrument used consisted of a Thermo Accela LC system interfaced to a Thermo TSQ Access triple quadrupole mass spectrometer with a HESI source. The data were processed with Xcalibur software (version 2.0). An amount of $10 \mu \mathrm{~L}$ of sample was analyzed in flow injection, with a flow rate of $0.2 \mathrm{~mL} / \mathrm{min}$ of mobile phase $0.1 \% \mathrm{HCOOC}$ in $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (50:50). Parameters used for the analysis in positive ion mode were: spray voltage 3500 V ; vaporizer temperature $300^{\circ} \mathrm{C}$; sheath gas pressure 50 au ; capillary temperature $350{ }^{\circ} \mathrm{C}$; capillary offset 35 .

### 3.2.1. General Procedure for Compounds $\mathbf{4 a , b}$

A mixture of 3 ( 0.35 mmol ) [35], a catalytic amount of $\mathrm{Et}_{3} \mathrm{~N}(0.1 \mathrm{~mL})$ and $\mathrm{SOCl}_{2}$ $(9.35 \mathrm{mmol})$ was stirred at room temperature for 30 min . Then the excess of $\mathrm{SOCl}_{2}$ was removed in vacuo and the residue oil was dissolved in cold anhydrous THF ( 1 mL ). To this suspension, the appropriate amine $(0.75 \mathrm{mmol})$ was added and the mixture was stirred at room temperature for 2 h . After cooling, cold water was added ( $2-5 \mathrm{~mL}$ ) and the suspension was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 15 \mathrm{~mL})$; the solvent was evaporated under vacuum to afford the desired final compounds, which were purified by flash column chromatography using cyclohexane/ethyl acetate 1:2 as eluent (4a), or by crystallization from ethanol (4b).

### 3.2.2. General Procedure for Compounds 5a,b

A mixture of $\mathbf{4 a , b}(0.43 \mathrm{mmol}), \mathrm{K}_{2} \mathrm{CO}_{3}(0.86 \mathrm{mmol})$ and 0.50 mmol of ethyl bromide in anhydrous DMF ( 2 mL ) was refluxed for 30-90 min. After cooling, the mixture was diluted with cold water ( 15 mL ) and compound $5 \mathbf{a}$ was recovered by filtration under vacuum. For compound $\mathbf{5 b}$ the suspension was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 15 \mathrm{~mL})$ and the solvent was evaporated in vacuo. The crude products were purified by crystallization from ethanol.

### 3.2.24. General Procedure for Compounds 31a,b

A mixture of appropriate pyridazin-benzonitrile 30a or $\mathbf{3 0 b}(0.165 \mathrm{mmol})$ and $80 \%$ $\mathrm{H} 2 \mathrm{SO} 4(2 \mathrm{~mL})$ was stirred at $80^{\circ} \mathrm{C}$ for 4 h . After cooling, ice/cold water ( $2-3 \mathrm{~mL}$ ) was
slowly added, the precipitate obtained was recovered by filtration under vacuum and purified by crystallization.
3.2.25. 3-(2-Methyl-3-oxo-6-phenyl-2,3-dihydro-pyridazin-4-ylamino)benzamide (31a)

Yield $=93 \% ; \mathrm{mp}=214-216^{\circ} \mathrm{C}$ (Cyclohexane). ${ }^{1} \mathrm{H}$ NMR ( 400 MHz, DMSO-d 6 ) $\delta 3.81$ (s, $\left.3 \mathrm{H}, \mathrm{CH}_{3}\right), 7.13\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{CH}\right.$ pyridaz.), $7.40-7.50\left(\mathrm{~m}, 5 \mathrm{H}, 4 \mathrm{H} \mathrm{Ar}+1 \mathrm{H} \mathrm{CONH}_{2}\right), 7.60(\mathrm{~d}, 1 \mathrm{H}$, Ar, J = 9.2 Hz), $7.64(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Ar}, \mathrm{J}=7.2 \mathrm{~Hz}), 7.76(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}, \mathrm{J}=8.0 \mathrm{~Hz}), 7.91(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}), 8.02$ (exch br s, $1 \mathrm{H}, \mathrm{CONH}_{2}$ ), 8.93 (exch br s, $1 \mathrm{H}, \mathrm{NH}$ ). 3.2.30. General procedure for compounds $\mathbf{3 7 a} \mathbf{a} \mathbf{d}$ and $\mathbf{4 2 a}, \mathbf{b}$

A suspension of appropriate pyridazinone $\mathbf{3 6 a - d}(1.29 \mathrm{mmol})$, commercially available, and hydrazine hydrate ( 48 mmol ) was stirred in a sealed/pressure vessel at $180-200{ }^{\circ} \mathrm{C}$ for 6-12 h. After cooling, ice-cold water was added ( 15 mL ) and the precipitate obtained was re-
covered by filtration under vacuum to obtain the desired compounds $37 \mathrm{a}-\mathrm{d}$. To obtain compounds $\mathbf{4 2 a}, \mathbf{b}$ we adopted the same procedure, using $\mathbf{4 1 a , b}$ (41a, [39]) as starting materials.

### 3.2.31. 4-Amino-6-thiophen-3-yl-pyridazin-3(2H)-one (37a)

### 3.3. Molecular Modeling and Biological Data

The 2D chemical structures were built using Marvin Sketch and all the structures were subjected to molecular mechanics energy minimization using the MMFF94 force field present in the same software [45]. The 3D geometry of all compounds was then optimized using the PM3 Hamiltonian [46], as implemented in MOPAC 2016 package assuming a pH of 7.0 [47]. Once built and optimized, all structures were used in the bioisostere replacement tool Spark 10.4.0. Five hundred compounds were generated for the substitution ( 50 best compounds reported in the Supplementary Materials). The isosteric replacement was performed using the same 178,558 fragments for each part; in particular, the fragments derive from ChEMBL and Zinc databases with a protocol already reported and validated $[27,48,49]$. Ligand growing experiments were performed in the selected pyridazinone structure using an already reported protocol [50]. Docking calculations were made using AutoDock with the default docking parameters and a validated protocol [51,52]. The setup was done with YASARA [47]. The Lamarckian genetic algorithm implemented in AutoDock was used for the calculations. The ligand-centered maps were generated by AutoGrid with a spacing of $0.375 \AA$ and dimensions that encompass all atoms extending $5 \AA$ from the surface of the ligand. All of the parameters were inserted at their default settings. The X-ray crystal structures of the co-crystal FABP4/(2-[(2-oxo-2-piperidin-1-ylethyl)sulfanyl]-6-(trifluoromethyl)pyrimidin-4-ol) (PDBid: 1TOU) was downloaded from the Protein Data Bank (www.rcsb.org accessed on 15 June 2022).

### 3.4. FABP Inhibitory Activity Assays

To analyze the inhibitory activity of FABP4 ligands, a displacement assay was utilized as described by the Cayman's instruction, FABP4 Inhibitor/Ligand Screening Assay Kit, Item 10,010,231 (see Supplementary Materials for additional details). The samples of compounds for activity determination were prepared as a stock solution ( 1 mM ) in DMSO. On the day of activity assay, the compounds were all diluted in phosphate buffer solution (PBS, pH 7.4) to different concentrations ( $100,50,10,5,2,1$, and $0 \mu \mathrm{M}$ ). Appropriate concentrations of DMSO in PBS were used as control. The detection reagent (FABP Assay Detection Reagent, Item 10010376) was used as provided by the Cayman's kit. The diluted Detection Reagent probe was mixed with FABP4 protein present in the kit and incubated for 10 min at room temperature. Compounds were then added and equilibrated for another 10 min . Lastly, the fluorescence signal was recorded at 470 nm (i.e., emission, with the excitation fixed at 370 nm ) with a CytoFluor ${ }^{\circledR}$ Series 4000 Fluorescence Multi-Well Plate Reader. The $\mathrm{IC}_{50}$ was calculated as indicated in the kit booklet of FABP4 Inhibitor/Ligand Screening Assay Kit (Item No. 10010231) Cayman chemicals, as follows: 1) calculate the average fluorescence of each sample; 2) calculate the background corrected fluorescence (BCF) by subtracting the blank; 3) divide the BCF of each sample by the maximum BCF and multiply by $100 \%$ (this is the value in percent fluorescence units, i.e., \% FU); 4) plot the $\% \mathrm{FU}$ values against the concentration of inhibitor/ligand used; 5) find the concentration of inhibitor/ligand that corresponds to $50 \% \mathrm{FU}$, to determine $\mathrm{IC}_{50}$ values.

## 4. Conclusions

We have identified novel 4-amino and 4-ureido pyridazinone-based FABP4 inhibitors whose design was directed by computing assisted molecular design of bioisosteric-replacements/ scaffold hopping of the pyrimidine skeleton of the co-crystallyzed ligand 1TOU. Selected compounds have been synthesized and tested for their ability to inhibit FABP4. Among the new series, ten compounds were further evaluated on the basis of their inhibitory activity on FABP4 established via a single point displacement assay. In particular, 4b, $\mathbf{2 5 a}, \mathbf{3 0 b}$ and 22 exhibited high FABP4 inhibitory activity with $\mathrm{IC}_{50}$ in the low micromolar range. The results demonstrated that compound 25 a was the most potent analogue in terms of displacement of the arachidonic acid, with an $\mathrm{IC}_{50}$ value of $2.97 \mu \mathrm{M}$, which is lower than the $\mathrm{IC}_{50}$ of the positive control $(3.42 \mu \mathrm{M})$. Docking experiments, conducted with the most active compounds $\mathbf{4 b}, \mathbf{2 5 a}, \mathbf{3 0 b}, \mathbf{2 2}$, confirmed the ability of these molecules to interact with several amino acid residues present inside the FABP4 binding pocket, with the stronger interaction exhibited by compound 25a. This result is in agreement with the higher activity recorded in vitro for $\mathbf{2 5 a}$, in comparison to the other 4-amino and 4-ureido pyridazinone-based analogues developed in this study.
