Biographical Note on authors:

*Oliver F. Glackin* has recently completed a MSc in the Psychology of Sport and Exercise at the University of Roehampton. Before that, he claimed a MSc in Psychology from the University of East London. Oliver is particularly interested in understanding individual’s experiences of exercising in natural environments, its influence on psychological well-being and how interventions can be designed to effectively harness its potential benefits.

*James T. Beale* is a BPS chartered psychologist and HCPC practitioner psychologist. James currently works at the University of East London where he has held an academic post since 2002. James is the current Programme Leader for the MSc in Applied Sport and Exercise Sciences. James has a specific research interest in the psychological mechanisms that underlie the benefits of exercising in natural environments.

**Funding:** This research received no specific grant from any funding agency.

'The world is best experienced at 18 mph'. The psychological wellbeing effects of cycling in the countryside: An Interpretative Phenomenological Analysis

Abstract
Green Exercise (GE) refers to physical activity conducted whilst simultaneously engaging the natural environment. A substantial body of literature has now been accumulated that establishes that carrying out exercise in this way has significantly greater psychological wellbeing benefits than the non-GE equivalent. Hitherto, seldom has consideration been given to the individual meanings that doing GE has. This study, therefore, sought to understand the lived experience of the phenomenon amongst a group of serious male recreational road bicyclists aged between mid-30s and early 50s who routinely rode in the countryside. Eleven bicyclists participated in semi-structured interviews. Data were analysed using Interpretative Phenomenological Analysis (IPA). This revealed themes of mastery and uncomplicated joys; my place to escape and rejuvenate; and alone but connected. Findings indicate that green-cycling served to enhance the participants’ sense of wellbeing and in doing so helped them cope with the mental challenges associated with their lives. It is suggested that green-cycling merges the essential qualities of natural surroundings – including its aesthetic, feelings of calm and a chance for exploration – with the potential for physical challenge and, facilitated by modern technology, opportunities for prosocial behaviours. It also identifies how green-cycling may influence self-determined behaviours towards exercise regulation, suggesting more satisfying and enduring exercise experiences.

Keywords: Green Exercise; green-cycling; wellbeing; Interpretive Phenomenological Analysis; Self-Determination Theory; nature
Introduction

The last decade has seen a rise in the overall numbers of people participating in recreational bicycling in the UK\(^1\). The roots of this increase appear to stem from several sources including its presence in public health campaigns. Bicycling is identified as an effective way of achieving the recommended level of exercise to improve physical and psychological wellbeing (UK Department of Health 2011, 2013, National Institute of Health and Care Excellence 2012, 2014). Bicycling is also commonly associated with the outdoors and as such can permit extended exposure to the natural environment. Green Exercise (GE) refers to the phenomenon in which physical activity is conducted in parallel to direct contact with nature (Pretty \textit{et al.} 2005).

Physical activity has been evidenced as making a material improvement to individual’s mental health – both in well populations (Harvey \textit{et al.} 2010) and amongst those suffering from diagnosed mental illnesses (e.g. Zschucke \textit{et al.} 2013). However, research shows how acute bouts of GE are substantially more beneficial to psychological wellbeing than the same exercise carried out indoors or in built outdoor environments (e.g. Bratman \textit{et al.} 2015). Specifically, it leads to further increases in self-esteem and mood (Pretty \textit{et al.} 2005); greater alleviation of depression (Barton \textit{et al.} 2012); more psychological restoration (Bodin and Hartig 2003); additional stress reduction (Hansmann \textit{et al.} 2007) and a lessening of state and trait cognitive anxiety (Marytn and Brymer 2016).

A number of theories have sought to explain how nature facilitates psychological wellbeing. Amongst these is Psycho-Evolutionary Theory (PET), which concerns stress reduction (Ulrich \textit{et al.} 1991). It emphasises how humans, when surrounded by visually pleasant scenes that include natural features, feel calm – moderating negative affect and summoning more positive emotions, such as joy. Another prominent and influential framework linking interactions with nature and psychological wellbeing is Attention Restoration Theory (ART) (Kaplan and Kaplan 1989). ART proposes that natural scenery is an inherently fascinating stimuli and engaging with it only captures involuntary attention (IA) – referred to by the Kaplans as soft fascination. As a result of IA, directed attention – a finite resource that is deployed when attending to cognitively taxing stimuli, including those encountered in urban or built settings – is restored (Kaplan and Berman 2010, Valtchanov and

\(^1\) Nearly 2 million people are reported to be riding their bicycles recreationally per week in England. Over 250,000 more adults are thought to be routinely partaking in recreational bicycle rides in 2016 than 2006 (Sport England 2016). British Cycling, the sport’s national governing body for the UK, is projecting a 21% year-on-year increase in membership (British Cycling 2015a).
In addition to cognitive fatigue, depleted directed attention is associated with negative affective states, such as withdrawal and irritability (Duvall and Sullivan 2016). Exposure to nature has been found to alleviate these (Berman et al. 2008) whilst simultaneously eliciting feelings of pleasure (see Pearson and Craig 2014 for a review), a finding replicated when carried out together with exercise (Calogiuri et al. 2015, Rogerson and Barton 2015).

Whilst crucially PET and ART offer explanations for nature’s restorative effects, they do not fully account for the additive influence of physical activity. In contrast, the Ecological Dynamics Approach (EDA) (Brymer et al. 2014) posits that natural environments provide more functional opportunities to undertake activities that might give challenging, complex and intense affordances, or invitations, which enables a range of emotions or behaviours to be experienced, such as confidence, calm and mindfulness. Building on EDA, Rogerson et al. (2016a) have proposed a model outlining how individuals perceive an environment’s affordances. The model incorporates three physical components: individual, exercise and environment. Acting upon each other they create a fourth element: an interactive processes component. This component comprises psychological and physiological processes within the individual that determines the facilitation or constraint of psychological affect (Rogerson et al. 2016a).

Despite steps to convincingly evidence the efficacy of GE and marshalling theories to explain its action; a gap in understanding how the individual directly experiences the phenomenon is acknowledged in literature (e.g. Martyn and Brymer 2016). Indeed, Rogerson and colleagues have referred to some of these phenomenological complexities as the ‘black box’ (Rogerson et al. 2016a, p. 177), thus heralding qualitative investigation. To the authors’ knowledge, few studies have expressly sought to qualitatively examine the experience of exercisers when engaging in GE, nor to take a bicyclist’s perspective. This limited understanding comes despite a substantial leap in recreational bicycling participation (Sport England 2016). The demographic held most responsible for this rise has been collectively labelled as MAMIL (Middle-Aged Man in Lycra) (Casciani 2010, Oxford English Dictionary), which is a perceptible sub-culture within road bicycling (Aldred et al. 2015). In addressing these gaps in knowledge, the study seeks to do so from the perspective of this burgeoning group – specifically those who prioritise green-cycling – as they typically devote substantial amounts of time and resource to the pursuit.

By using Interpretative Phenomenological Analysis (IPA) to examine in detail this group and how they make sense of their green-cycling experience, it should be possible to
better understand the meanings it has for them. What specific aspects enrich the activity and how it might be perceived to influence their lives. Going further, it is contended that this study may give rise to some insights for practitioners and policy makers into effective ways nature might be incorporated into physical activity to further enhance its positive effects. Accordingly, the overarching aim was to explore how male, middle-aged, serious recreational bicyclists experience riding in the countryside and the unique meanings it holds for them. Additionally, it sought to examine the importance of green-cycling to perceived psychological state and identify the ways it influences attitudes to road bicycling.

Method

Methodology and philosophical underpinnings

Interpretative Phenomenological Analysis (IPA) draws together three areas of the philosophy of knowledge: phenomenology; hermeneutics; and idiography (Eatough and Smith 2008). It seeks to discover how individuals ‘are making sense of their personal and social world’ (Smith and Osborn 2008, p. 53). Reflecting the study’s aim to understand the individual’s experience of green-cycling and both the novelty of the pursuit and the seemingly complex motivations of the group, IPA was considered appropriate. For IPA, meanings and beliefs manifest in talk or writing. By analysing these words, the essence of the unique lived experience might be traced (Smith and Osborn 2008). IPA adopts a duel interpretive process, described as the double hermeneutic, whereby the researcher makes sense of the participant making sense of their experience (Eatough and Smith 2008, Shaw 2010). Accordingly, IPA recognises both the subjectivity of the participant’s and the researcher’s experience and hence the speculative character of the analysis process (Smith et al. 2009). Whilst the centrality of the individual’s experience is prized in IPA, its procedures, nonetheless, allow for generalisations to be drawn, albeit cautiously. Indeed, Smith and colleagues have explained how IPA’s focus on the ‘details of the individual… brings us closer to significant aspects of the general’ (2009, p.32). Thus in doing so, it can further enlighten existing nomothetic research (Smith et al. 2009).

Participants

In line with IPA, purposive sampling was conducted. This sought males who identified as road bicyclists and fell within the age bracket mid 30s and early 50s. These parameters were
set to align with the demographic responsible for driving the growth in UK recreational road
cycling (British Cycling Factsheet 2015b). Additionally, participants had to be professionally
employed, not primarily motivated by formal competition but riding road-racing bicycles in
the countryside once a week with direct exposure lasting longer than an hour for the past two
years. Distinctions such as whether they rode alone or in groups and the use of tracking
technology did not feature in the selection criteria. The countryside was determined to be any
outdoor environment perceived to be rural, away from urbanisation, where landscape features
associated with nature were extensively predominant but which could be traversed by road. It
was assumed that the cyclists’ age and backgrounds would require them to negotiate and
balance riding with other responsibilities, such as work and family demands. Due to the high
degree of personal time and resource invested, it was also assumed that it was important to the
participants.

On receiving University Ethics Board approval, men were recruited through postings
on cycling-related online forums. Those expressing an interest were given an information
sheet outlining the nature of the research and the inclusion criteria. Participants were made
aware that involvement was voluntary and that they had the right to withdraw at any time. To
ensure anonymity pseudonyms were used throughout. Participants were 11 male recreational
road cyclists aged between 34 and 52 years ($M_{age} = 40.18$ years, $SD = 6.45$). All identified
themselves as meeting the criteria for selection, an overview is provided (Table 1).

Data Collection
On giving consent, all the participants were involved in a confidential interview conducted at a time and place of their convenience this reflected the busy professional schedules many kept. Eight were held in meeting rooms located in open-plan offices where they worked, two were carried out at participants’ homes, whilst one was completed in a public place where privacy was assured. All reasonably practicable steps were taken to ensure the safety and security of the researcher and participants.

A semi-structured interview framework was deployed. This is considered to be the ‘exemplary method for IPA’ (Smith and Osborn 2008, p. 57) as participants are encouraged to explore their experience and empowered to determine the shape of the story they tell. The interview schedule was created based on the principles set out by Smith and Osborn (2008).

This encourages the development of an order of questions which amounts to a guide rather than a list to be rigidly followed. The attendant flexibility enables the interviewer to modify existing questions as necessary to pursue novel and interesting lines of enquiry as they emerge (Eatough and Smith 2008). The interview schedule focused on three broad areas of the participants’ experience covering: relationship with road bicycling; influence of the countryside; and identity. Each interview was digitally-recorded and ranged from 35 minutes to 1 hour and 15 minutes in length. The recordings were later transcribed verbatim.

Data analysis
Adopting the guidelines set out by Smith and Osborn (2008) and Shaw (2010), the transcripts were initially analysed by the lead author. To do this, the following stages were applied. A transcript was read multiple times to establish a deep familiarity with the data. Once acquainted, descriptive summaries of significant or interesting comments articulated by the participant were noted. Following this, initial interpretations of what the descriptions might mean were made. This sought to draw out the essential elements contained in the sections of
Following the listing of initial themes, a process of clustering took place which consolidated themes of similar meaning. From this clustering emerged central concepts – or superordinate and subordinate themes (Shaw 2010). To demonstrate how all the interpretive themes were represented in the data, relevant excerpts from the transcript were highlighted. Whilst each further transcript was analysed independently as described above, reflecting the number of participants involved, the themes developed in earlier cases were used to appraise each subsequent analysis (Smith and Osborn 2008). This meant identifying repeating patterns, convergences, as well as divergences, where new issues came to light. At the end of the interpretation process, a list of superordinate and associated subordinate themes drawn from all the participants were tabulated for final selection. This involved merging certain themes that were conceptually similar and removing those felt to be comparatively weaker. Illustrative quotes from the participants’ accounts were linked to all the remaining themes. The final stage of analysis required shepherding the substantive themes into a narrative account that articulated the findings. It was evident that some analysis of the themes continued as they were formed in the writing process.

Throughout the analysis, the principal author kept a reflective diary (Shaw 2010). In addition to capturing thinking about developing interpretations, it also provided a record of acknowledged biases which were subsequently suspended in relation to the data (Lemon and Taylor 1997). For instance, this process revealed the assumption that competition would represent a significant feature of the participants’ experiences and that the use of technology would fuel this further. Complementing this, the co-author acted as a critical friend surveying theme development within and between cases to ensure credibility against the data. This consisted of challenging and clarifying how the links between the data, abstract theorising and, finally, extant psychological literature were justified. This process resulted in the further development and refinement of final themes.

**Results and Discussion**

The analysis identified three recurrent superordinate themes and the subordinate themes they incorporate. They relate to the participants’ experience of green-cycling and the meanings it had for them. The participants spoke of: mastery and uncomplicated joys; my place to escape and rejuvenate; and alone but connected. Elaboration on these themes is presented below.
Mastery and uncomplicated joys

This theme is split into two subordinate themes. My place to marvel, which addresses the occasions the participants described the values and meanings associated with the extended distances that cycling in the countryside encourages. Second, simple joys which concerns the feelings aroused by the physically challenging and thrilling terrains that are negotiated.

My place to marvel

The theme my place to marvel relates to how for the participants the countryside formed a backdrop for articulating the personal pride they felt about their accomplishments on the bicycle and how it acted as a gauge of and motivation for mastery. The special meanings this place had in contrast to less rural environments was captured by Sean, ‘It’s all about the countryside! I mean I kind of ride in and around [urban] Park, I do that out of necessity because I feel that that's the place to go, kind of do, like a quick fix’. There was a sense of urban riding being perfunctory, as Richard put it, ‘a chore’ – merely a way of sustaining fitness. Elaborating further on the elements that ensure the countryside enhances the physical experience of bicycling, Francis said, ‘I think the workout you get from your ride in the countryside is a lot better. There's more hills obviously, they're country lanes so different gradients – a more varied workout’.

Unlike Francis, when considering the virtues of the countryside, several of the participants initially focused on the distances it encourages to be ridden, which were all documented. Logging of mileage acted as a tangible record of performance and improvement. As Andy put it, ‘I got how many miles I'd done for the year it was like wow! A sort of sense of achievement and frankly using the time usefully’. Uniquely, Andy prioritised the experience of road-riding and its association with physical mastery over other factors explaining, ‘which direction… I’m going in doesn’t matter… I don’t care, I just want to ride my bike’. Perhaps significantly, Andy was the only participant who lived in a rural village meaning all his riding was green-cycling. This potentially altered the meanings that seeking out nature represented compared to the others. However, when contrasting green-cycling with doing it indoors, he identified how, ‘you miss that undulation and the variety of exercise…[it] just, doesn’t motivate in the same way’. In acknowledging the difference, it is possible to deduce that the countryside offered more to the participants than endless tarmac to ride miles
on. Philip shed further light on what function distances might serve amidst goal progression and its relationship with being in the countryside:

…as that kind of having goals are concerned… I guess it's exploring bigger more beautiful places… riding big routes, and up big hills and just seeing all that beautiful countryside… Having big days out on the bike. You cover big distances, going to the Alps, you know, it's bigger, it's harder, it's more beautiful.

Philip’s description of how distance formed just one element of a broader and interwoven challenge concept was typical of nearly all the cyclists including Alex who agreed:

Even a decent but not great road cyclist can do 100 miles. Which in the mountains is a significant chunk you could see loads of different valleys, you can go over lots of different passes and that idea that there's always something to see around the next corner, over the crest of the next hill, climb one mountain down the other side and you're in somewhere you've not seen before. That's a very resonant idea for me.

Reflecting the surroundings, cycling is perhaps unique in providing a mix of dynamic challenges. These can become progressively more difficult over time and mastery is dependent on developing certain competencies and skills – some obvious – such as greater stamina and bicycle maintenance knowledge – and others subtler – including mental fortitude and bicycle handling. Supporting this notion, David shared:

I've conquered routes and climbs that I wouldn't of done or would have struggled with before and found those getting easier, as I've accepted my abject fear of going downhill and kind of learnt to bottle that and keep that under control. I've become as a person a lot more self-confident.

A virtuous circle seemed to have established for the participants whereby the capability to cover and enjoy more terrain is dependent on greater stamina and strength which contributes to growing physical competence that gives confidence to further explore the natural environment. This finding appears to support the Ecological Dynamics Approach (Brymer et al. 2014), with the countryside here playing an active role in affording the participants the opportunity and freedom to constantly challenge themselves not simply physically but also emotionally resulting in positive psychological experiences.

What was also striking was how Philip, reflecting other participants, characterised the challenges with which they set themselves as, ‘sensible’ and as Francis put it being, ‘naturally drawn to keep doing it’. Two participants did refer to more external drives, in this instance health promotion. David and Andy disclosed that physical activity formed part of a regime to manage chronic medical conditions with the former – a Type-1 Diabetic – explaining how green-cycling helps because it, ‘feels, well it just feels, better – it’s easier to do’. Joe,
however, rejected the notion of doing it because of external pressures drawing a clear
distinction saying, ‘I will... do a cycle because I’ve learnt to enjoy the cycle itself’.

The order with which external pressures spurred the participants’ activities typically
appeared to be secondary to their own internal desires to bicycle surrounded by nature. It may
be possible, therefore, to broadly characterise the type of motivation present amongst the
group as self-determined. This experience that the participants spoke off in the present study
appears to align with Deci and Ryan’s Self-Determination Theory (SDT) (2008).

Incorporating SDT into the Green Exercise paradigm marks a significant departure
from extant literature, nonetheless in the context of physical activity its relevance has been
established (e.g. Lindwall et al. 2016). As a result, this macro-theory might provide a useful
framework when considering the interplay between exercise and the natural surroundings
which brings about its recognised additive benefits, a gap identified by Ewert et al. (2014), in
addition to potentially helping inform the interactive processes component identified by
Rogerson et al. (2016). SDT focuses on types of motivation, paying particular attention to
autonomous motivation, controlled motivation, and amotivation the first being the best
predictor of elevated performance, relational, and wellbeing outcomes (see Teixeira et al.
2012 for a review). It also addresses the social conditions that enhance these types of
motivation, emphasising autonomy, competence, and relatedness (Deci and Ryan 2008).

For the participants in this study, the countryside might be interpreted as a rare space
containing the nutriments where a series of predominantly self-determined repertoires could
be played out, such as independently defined achievement, personal growth, physical
empowerment and health, volition to explore and enjoyment. This finding contributes to
existing literature focused on exercise motivation (Sebire et al. 2009, Gunnell et al. 2014),
suggesting more self-determined exercise regulation results in enhanced exercise persistence
and greater psychological wellbeing. Consequently, there might be merit in further research
examining whether incorporating natural landscape features into physical activity regimes
contributes to more inherently satisfying experiences.

\textit{Simple joys}

All the men described the fun, thrill and the physically embodied feelings of joy they felt when
riding in the countryside. As Stephen put it:

It feels natural. You feel like you’re expressing yourself when you’re doing it on a
physical level and I do feel that about being on a bike and definitely get that thing.
Yeah, there’s the exhilaration of going fast. Yeah, it’s fantastic because it’s not like
a rollercoaster but there’s enough thrill to make you feel like a kid again. Like
there’s a part of you that’s going: weeeeee! As you go down you know it’s really
uncomplicated and really simple.

Alex also highlighted the draw that certain roads and hills had as well as the part that the
natural aesthetic played in accentuating the sensation, saying, ‘There's some roads which are
really fun… You’re going downhill forever and it's very beautiful and you're just on the edge’.
There is a sense of getting pleasure from gratifying an inherently human urge (Coveney and
Bunton 2003). Like Stephen, references to childhood were typical amongst the participants
when describing the pleasures they experienced. For instance, Andy opened his interview
articulating how, ‘I used to cycle a lot I think as a kid and used to enjoy getting out’. One of
the features that characterised that enjoyment was the freedom to reach high speeds, which
continued to fascinate into adulthood. As Joe said:

I like descending hills because it's exciting, because you go fast. There’s sort of a
bit of risk… It is fun, descending at speed. I suppose I used to ride a bike when I
was a kid… because I used to enjoy riding.

Sean, who was a former Royal Marine, also emphasised how this pleasure was in part
predicated on the ability to simultaneously invite and then tame the hazard, ‘If I'm going
downhill, it feels like you're competing against yourself. if you're doing a downhill descent
you know you're roughly hitting – 50, 60,70 km's an hour it's like, ooh, that feels quite
dangerous’.

Indulging in frissons and harking back to earlier times appears to give credence to the
conception that cycling in the countryside was a simple joy for the participants – echoing the
findings of Minello and Dixon’s (2017) study of older male cyclists. Indeed, even wretched
weather conditions could not dampen these emotions, as David put it: ‘It was absolutely
brilliant. It wasn't relaxing, it was freezing cold 20 mph winds, lashing rain. When you came
back it was like that old analogy about banging your head against the wall. It was lovely when
you stopped’. The impression that justification for the fun was not necessary and the apparent
irrationality at some moments to its potential consequences including censor was summed up
by Stephen, ‘I just absolutely love it. You know, it’s worth risking marital discord to make it
happen… As a person, I’m happy with life, if I can do rides like that’.

There is evidence here to support Biddle and Mutrie (2007) who contend that
enjoyment, intrinsic motivation and the concept of Flow coexist in relation to physical activity.
Many of the accounts also support the Flow concept (Nakamura and Csikszentmihalyi 2009)
where high-speeds precipitate an autotelic experience and the pleasurable sensations
associated with being absorbed in the present moment by challenges that stretch but do not exceed existing skills and where clear goals and immediate feedback are available.

As we have seen, drawing attention to the sensations they experienced as part of a ride and the way it made them feel was commonplace in the participants’ talk. For instance, Alex said:

You get to the top and it's pretty win dy up there. you'd get this real sense of being hit by nature, and hit by the natural world and that was definitely a, something I'd look forward to… [it] was a big motivation, a lot of the time. You spend the day at the desk and just have it all blown away by the time you get to the top of the hill.

Like the sensual type of pleasure identified by Phoenix and Orr (2014), there appeared to be a coming together of the body and the world in many of the participants’ accounts which leaves them at the influence of their present exercise environment. Furthermore, based on anthropological observations of older-age Italian road bicyclists, Whitaker (2005) has posited that the experience of riding in the countryside uniquely merges body and soul which culminates in an intense joy that is not limited to the present but also reaches into time off the bike, corresponding with heightened wellbeing. Echoing this, Joe, reflected on his green-cycling experience, saying, ‘After a long ride [in the countryside], you'd come back.... You feel good about it. You feel very optimistic, and it sets you up for the days ahead’. The present study’s findings, albeit amongst a younger cohort, further reinforces the earlier works’ recommendations that emphasising the pleasurable elements of exercise may help promote behaviour change towards increased physical activity (Whitaker 2005, Phoenix and Orr 2014). As Patrick put it, ‘I do it because I enjoy it and I do it because it makes me feel better, both physically and mentally’. Accordingly, policy makers and practitioners should consider the potential opportunities that features of the natural environment might provide to allow for the effective integration of pleasure experiences into physical exercise activities.

*My place to escape and rejuvenate*

A number of the participants reported how they viewed the countryside as somewhere to escape to and recuperate in. Accordingly, two subordinate themes: unhindered exploration and the rhythm of restoration were arrived at.

*Unhindered exploration*
Reflections on how green-cycling offered a potential fillip to mental wellbeing featured prominently across all the participants’ accounts, for example Sean, ‘I’ve kind of always felt like getting on a bike feels like escaping’, and Francis, ‘getting out there [the countryside], and nothing to worry about’. Some identified what precisely they wanted to leave behind. Like Alex, ‘there’s often that sense of a big long ride as a release after a stint of work’, and Leon, ‘there’s a definite correlation between the time that my partner and I had our daughter and when I started cycling longer and further’. Elaborating on his desire to get away Leon highlighted his quest for solitude, ‘it’s just me on my bike, doing something positive and life affirming’. The absence of other people, also implied safety from motorists. This feeling of safety served to enable the surroundings to be attended to in an incautious way, as David explained:

I feel much more relaxed in a rural setting, on the bike… when you're out on a quiet road, rolling hills, all that kind of thing you focus, you’re able to focus to a far greater degree on your riding and your surroundings.

This finding corresponds with Ulrich (1979, 1983, 1984) and Ulrich et al. (1991) Psycho-Evolutionary Theory (PET) that suggests the salutogenic benefits of the aesthetic are only activated when distractions and dangers are minimised (Hartig et al. 2011).

Most of the participants also maintained how getting away into the countryside satisfied a need to explore pleasant scenery. As Joe put it:

It’s sort of a better experience. But then I think it's just sort of nice to be out in the countryside, you sort of know the sun coming up or a bit of mist or the smell of wood smoke or something from a fire. It all just adds to the sense of freedom and being out on the road and kind of exploring.

It is noteworthy that Joe was the only participant who was also a serious runner – frequently inferring that it was a more efficient means of getting the physical health-related benefits of exercise. However, it was clear in his account, and exemplified above, that running did not necessarily permit the psychological engagement with the surroundings that was so valued. Joe’s experience reflects Rogerson and colleagues (2016a) speculation that in instances where internally focussed exercise cues predominate, receptiveness to the environment might be limited. Comparisons were also drawn with mountain biking by two of the participants. Richard, who had previously been a keen mountain biker in his youth but had switched to road cycling later, explained:
Road cycling, well you just go wherever you want and I think that's a really incredible thing. You can start a ride with a general direction and just get lost you know and find your way back and I really like that. It's slightly easier to do that on a road bike than on a mountain bike.

And Alex, who said, ‘With mountain bikes, you simply can’t cover enough terrain’, drawing attention again to the allure of, as he put it, ‘increasing your knowledge of the landscape and of the geography and the sights and smells’.

The participants’ experiences appear to accord with Attention Restoration Theory (ART) (Kaplan and Kaplan 1989, Kaplan 1995). Hitherto, literature has prioritised the influence of soft fascination – where attention is effortlessly captured principally by exploring and making sense of the environment – and its influence on psychological restoration. However, ART identifies three additional features that an environment should have to afford soft fascination. These concern the notions of: being away or a need to feel escape from the stressful demands of daily life; extent, that is the environment has sufficient scope to facilitate a sense of mental unfurling; and compatibility – which stresses how the surroundings must accommodate a person’s inclinations, needs and purposes in that moment (e.g. Duvall and Sullivan 2016). The current study has revealed both the presence and significance of these phenomena in the experiences of many of the participants.

As previously identified, the road bicycle was considered an essential facilitator of exploration, immersion and a sense of interaction with the natural aesthetic. Participants gave practical explanations for this including its cruising speed, vantage point allowing hedges to be overlooked as well as its quietness. The culmination of these qualities meant the bicycle permitted a full sensory experience. As Stephen elaborated, ‘The world is best experienced at 18 mph because you see more stuff than if you’re walking but you see it better than if you’re zooming past on a train… I completely get that... It’s big!’. Stephen’s comments appear to touch on PET’s conception of humans as being ‘hard-wired’ (Hartig 2007, p. 166) to perceive the pleasantness of natural environments. This point was most pithily put by Leon when he exclaimed, ‘This [the countryside] is fucking lovely isn't it. I don't think anything more profound than that… it makes you feel lucky’. Whilst Deci and Ryan (2000) have posited that curiosity-based exploration and openness to sensory experiences of nature are activities that require the satisfaction of basic psychological needs to operate optimally, there appeared to be a more essential underpinning to the participants’ accounts. Most of all that green-cycling was a conduit to a richer and more meaningful interaction with nature and with it lived experience.

This finding corresponds with the biophilia hypothesis (Wilson 1984, Kellert and Wilson,
which posits that humans feel an inherent connection to nature and that ‘the good life’ (Kellert 1993, p. 60) is in part derived from our evaluation of it. The essence of this was perhaps best captured by Leon:

Maybe it's about majesty, or being reminded that it’s, there's more. That earth is about more than all the crap that we see every day from our houses to the train station, to wander around town and supermarkets and all that crap, there's something more essential about it.

The rhythm of restoration

The participants consistently spoke about how green-cycling encouraged a relaxed psychological state. Stephen outlines what this meant:

I get quite quickly into a nice rhythm on the bike and when you’re into a nice physical rhythm you get into a different mental state… I don’t think about very much. I quite often think I’m going to think about stuff on a long ride and I end up thinking fuck all, really… A song will go through my head… I’m not a spiritual person… [cycling in the countryside] invites a sort of mindfulness where particularly if you’re not challenged by traffic… you’re in quite an unbuttered medical state, you’re doing your thing, you’re at one level absorbing it. You’re not noting your physical state you’re noticing the environmental, you know surroundings, you’re not at intellectual full pelt, or anywhere near it, but you are on!

In this extract we find traces of pleasure from immersion. A concept whereby movement serves to bring together the body and mind which precipitates a detachment from daily concerns or a focus on one’s self (Phoenix and Orr 2014). Further evidence of this was offered by Richard, ‘I think it allows you to, the countryside allows me to focus on, prff! I don't know what, but to focus. You feel, even when you're with friends, like you are on your own’. The presence of mindfulness is also referenced, however. Mindfulness is postulated to be an enhanced awareness of present experience and functioning characterised by “clarity and vividness” (Brown and Ryan 2003, p. 823). It is also correlated with greater nature connectedness (Howell et al. 2011). Hence it may be possible to point to a sequence by which green-cycling advances a state of mindful consciousness that in turn encourages greater awareness and amplification of nature and its psychological influence.

Stephen and Richard’s experiences also appears to give credence to the notion of ‘clearing the head’ identified in ART (Kaplan and Kaplan 1989, p. 196). Permitted by the untaxed environment, it is understood to be accompanied by the entering of random thoughts into the mind. Like songs intruding upon Stephen’s awareness above, other participants reported similar experiences, including Patrick:
I often have tunes coming into my head that are quite bizarre… music that I wouldn't listen to. Hymns, I'm an atheist… but I have hymns coming into my head! Weird songs that I've never, you just suddenly stop yourself and think what the hell, where's that come from?

Although Leon highlighted how this phenomenon could be subverted on occasions when, ‘I get a bad song stuck in my head that can be irritating’. The allusions to religion referred to in the reflections of Stephen and Patrick, above, as well as in Francis’ narrative, ‘I feel really blessed [when I am cycling in the countryside] - I don't believe in God or anything’, also draws attention to seeming transcendence for some. Indeed, parallels between the characteristics of Flow and aspects of Zen philosophy, particularly meditation, amongst rock climbers have been drawn (Csikszentmihalyi 1975, Watson and Nesti 2007). Notably however, Philip, a seasoned rock climber, contrasted his experiences of the countryside when climbing with cycling saying, ‘it's very unlike climbing. At that moment climbing, it's so intense, there's no room for anything, so it's a different type of thing for your brain’. This draws attention to perhaps an important feature of green-cycling; that it benefits from enabling the prospect of exhilarating thrills and quiet reverie to be juxtaposed efficiently and effectively. Touching on this point, David said:

There’s moments on the Sunday rides…you're not worried about whether you filed those papers or whether you're going to make that deadline, all that kind of stuff. You're right there and that includes being aware of the birds singing, the leaf mold, all that kind of thing.

For David, like many of the other men, the process of mental unfurling when green-cycling helped them to cope emotionally with their day-to-day challenges. Alex offered a further account of this process:

I've hit a problem or something… I’ll ride and I'll try and think about this block that I've got. But often I don't think about anything at all. I just suddenly get into a state where nothing really goes through my head. And that is as useful and as therapeutic… I find that incredibly cleansing… I know that it's going to be a positive mental experience.

Uniquely, Philip, spoke of how green-cycling did allow for conscious thinking saying, ‘on longer rides you can ride big stretches, I … have, a really good opportunity to think things through slowly and in a nice kind of considered, natural way…. it's just a great opportunity to go over stuff’. This echoes the Kaplans (1989) who posit that the last and deepest restorative stage in ART involves reflections on life goals. However, its absence from the other participants’ accounts casts some doubt over its relevance to feelings of restoration – and like
many of the facets of ART, notwithstanding fascination, there is merit in its further investigation.

The excerpts above signal how the typical view amongst the participants was that routine exposure to green-cycling was invaluable. As Francis put it, ‘If I didn’t do [green] cycling [every weekend] then I wouldn’t perform as well at work or in my everyday life’. And Patrick, ‘It makes me a better person… if I didn't have the cycling, and I didn't have that vent, I wouldn't be as happy… my whole wellbeing feels better when I've been out on my bike’. Exercise, the natural environment and wellbeing seemed to be perceived as three inseparable entities. As Leon explained, ‘If I couldn't ride out into the [countryside], I'd feel really sad. Like it would be a massive hole in my life’, and Alex corroborated, ‘I guess I'd probably have to find an alternative way of doing, finding the same experience and doing the same thing. I wouldn't ride a spinning bike, I wouldn't be happy going to the gym’. For all the men, sustaining a regular green-cycling regime was essential – this meant green rides at least once a week that were several hours in duration. The effects were considered cumulative and were seemingly psychologically therapeutic. This notion was particularly pronounced for Sean, who had recently recovered from a serious leg injury:

I've had two months of sitting around in the flat of just mental and physical pain and suffering and whinging. The one thing I was desperate to do was just get on a bike and go out towards the countryside… that's the one thing I kept wanting to do.

Barton and Pretty (2010) have advanced the efficacy of short exposure times – five minutes – to achieve the benefits of GE. However, as acknowledged in literature and evidenced in this study, some individual preference may exist that influences this response, specifically in relation to intensity, duration and quality of nature experience (Barton et al. 2016).

Alone but connected
A number of the participants expressed how they viewed bicycling in the countryside as an activity that when done alone was routinely enhanced by the experience but never diminished. As Alex said, ‘what I prefer doing is getting out, often on my own’, with Joe confirming, ‘I mean I do enjoy riding with people, but equally I’ll get as much enjoyment from being on my own’. What this does not account for were the occasions when participants did identify associative qualities they appreciated when bicycling in nature – particularly in the virtual sphere.

Significantly, the adoption of technology formed an important part of how participants experienced their green-cycling relationships. Using bike-mounted computers, every
participant gathered a set of performance data about their ride as well as GPS-based route
mapping. Technology was synonymous with riding, as David put it, 'It’s great and I can’t
imagine getting on the bike without it’. Collected data was routinely shared publically
through online sites after a ride. These sites encourage comparisons with others, thus
theoretically inviting competition. Some resistance to this was apparent, as Patrick reflected,
‘it was better before I used it [online site], but I wouldn't dream of not using it’. Explaining
his initial concerns, he added, ‘Having [online site] made me push a bit more. It introduced a
bit of competition that I didn’t like. I don’t do it for the competition’. Providing more insight
into what the sites typically meant to the participants and how they had come to negotiate it,
Philip said ‘It’s [online data sharing] quite encouraging and quite inspiring, I think. I’m
always inspired more by my friends’. This finding extends research into amateur sports
cyclist’s motivations (O’Connor and Brown 2007, Brown et al. 2009) by suggesting a more
nuanced relationship with competition amongst those prioritising green-cycling. Rather than
rivals, other cyclists were considered as equals, guides to achieving a better experience.
Also noteworthy is that whilst the technology encouraged real-time engagement by
virtually comparing one’s pace over sections of road, most of the participants quickly
disregarded this. The reason, Leon explained was because, 'It's about having a nice bike ride
rather than thinking… I’m going to meaninglessly compete against people that I've never
met’. Instead, it was often viewed as a navigation aid as Stephen confirmed, ‘I just use the
[bike computer] to make sure I don’t get lost’. Attending to its implications for promoting the
green-cycling experience, Alex explained, ‘What I like it [data sharing websites] for is
exploring by proxy, and seeing what other people are doing… I can take inspiration from their
routes, when I'm planning something I want to do myself’. This point was further emphasised
by Patrick when he said:

A lot of friends who ride are on [data sharing website]… you have that link up
with people. I wouldn't drop them a text and just say hello, but I get messages
from them about the ride that I’ve been on, asking me where I've been, saying it
was a good ride. You put pictures on there, I've got this thing going with a friend
where he started taking photographs of old red post boxes and posts them and
when I'm out riding I can't help it if I see one.

Technology appears to have given the bicyclists a means of identifying new areas of
countryside to explore and new ways of engaging with it. Doing this appeared to nourish
enthusiasm resulting in more riding and with it greater exposure to bicycling and the
environment. Simultaneously, however, online sites also enabled the cyclists to remain
connected with others and benefit positively from sharing the pleasures experienced when
e xplo ring the countryside as Patrick’s vignette explained.

This finding aligns with Rogerson et al. (2016b) who have identified how GE may
 promote prosocial interactions. Limited attention has been given to how modern technology
could enhance this positive benefit further, however. There is also some evidence in the
present study that sharing information about cycle routes in nature and the data associated with
that enhanced the pleasures derived from the activity. This finding echoes Phoenix and Orr
(2014) who contend that documenting physical activities can boost feelings of pleasure,
particularly after the event, and sharing details of the experience may bolster affect further.
The present study also suggests that when using technology, participants generally eschewed
negative comparisons with others or to perceive it as an impetus for extraneous competition.
There are parallels here with Deci and Ryan (1985), most notably their assertion that activities
interpreted as informational rather than controlling promote feelings of autonomy and
competence and thus encourages self-determined motivation and with it positive affect.
Accordingly, practitioners seeking to implement strategies to drive up physical activity, should
consider exploring how they might use technology to encourage the sharing of individual
experiences of nature when exercising.

**Reflexive analysis**

The genesis of this research was the principal author’s own interest in the topic. As a
longstanding road bicyclist they had observed its rise in popularity. Whilst not disclosing their
bicycling biography to participants before or during the interview process, it should be
acknowledged that the framing of questions and the familiarity with road-riding parlance
would have revealed that they were experienced in the subject matter, which could have
influenced participants. Also noteworthy was that whilst the co-author was conversant with the
major theoretical concepts underpinning sports and exercise psychology, the first was less so.
The implications of this are pertinent here considering that Self-Determination Theory appears
for the first time in the results section. This sequence reflects how its potential significance in
understanding GE only emerged following the interpretation of the participants’ data. As with
all the principal author’s interpretations, the co-author played a crucial role in challenging
these, particularly the emergence of Self-Determination Theory because of its novelty.
Checking it against the data they could satisfy themselves of its relevance and credibility.
Limitations and future directions

The present study did not actively seek participant validation (Mays and Pope 2000). The absence of follow-up interviews or an attempt to get them to review the investigators’ interpretation of their accounts may have detrimentally affected the overall credibility and validity of the work.

The study’s findings represent insights into a particular group. Demographic factors such as age, gender, social-class and ethnicity, may also influence how GE is experienced, however the evidence is limited (Wood et al. 2016). Therefore, to better appreciate its effects; the barriers to accessing it; and how it might be more effectively harnessed, there is an identified need to consider the experiences of other groups. This should result in other types of GE being investigated. This study raises the possible association between nature and the experiencing of enhanced levels of self-determined regulation amongst physically active individuals. The strength of this link merits further investigation as it could augment the current understanding of motivations for exercise and how surroundings can be fashioned to increase enjoyment, wider affect and encourage perseverance.

Conclusion

This study of male, middle-aged, serious recreational bicyclists has revealed cycling in the countryside to be a multifaceted experience. For the participants, it appeared to merge several essential qualities – these were: volition in selecting one’s physical challenges; opportunities to feel pleasure; the chance to engage with natural aesthetics; to experience mindful awareness; and to enjoy solitude yet also connect with others. Combined, these culminated to boost the participants’ perceived psychological wellbeing not only in the immediacy of green-cycling but afterwards also. Identifying this interplay may go some way to help understand the observed additive benefits that GE offers and to provide insights into how aspects may potentially be incorporated to create more effective and enduring physical activity regimes. The present study has opened new avenues that warrant further investigation including nature’s potential to engage more self-determined behaviours.
